

QR-04c: Failed deployment should automatically roll back to the last live revision

The top screenshot shows the GitHub Actions interface for the 'UniTrade Pipeline' run 'pls work #32'. The 'deploy' job is highlighted, and the 'deploy-staging' step is shown as failed. The job summary indicates '1 error and 1 warning'. The 'Annotations' section shows the job failed 2 hours ago in 2m 11s. The 'Run details' section shows the following steps:

- Set up job (1s)
- Checkout code (2s)
- Login to Azure (11s)
- Setup .NET (1s)
- Install EF tool (7s)
- restore dependencies (8s)

The bottom screenshot shows the 'deploy / deploy-staging' job details. The 'Deploy backend green revision' step is highlighted, showing an error: 'ERROR: (ContainerAppSecretInvalid) Invalid Request: Container app secret(s) with name(s) 'signalr-conn' are invalid: value or keyVaultUrl and identity should be provided.' The 'Rollback to previous revisions (failure event)' step is shown as successful, indicating that the pipeline automatically rolled back to the previous revision.

The CD pipeline deploys each new revision as a green revision alongside the live blue one. Before shifting traffic, the pipeline runs a health check against the green revision. If it fails and if failure step restores 100% traffic to the previous healthy revision and deactivates the failed green one so a broken deployment never reaches users.

Evidence the screenshot shows a pipeline run where the green revision failed its gate. The rollback step then executed restoring traffic to the previous revision. Staging remained available throughout.

As a result, the failed deployment did not take down the live environment traffic, it was just auto restored to the last healthy revision.
